CaseProof

Fewer rounds of paperwork in small business finance

Project proposal | AI Builder Cup 2026 | 24 September 2026

Theme: Banking, financial services and insurance (BFSI)

The problem

A small business can borrow against an unpaid invoice while it waits for its customer to pay. The lender may need supporting documents before releasing the money. DBS, for example, says customers who already have an approved financing arrangement usually need to submit an invoice and proof of delivery to use it. [1]

The difficult part starts when those records disagree. An invoice might charge for 100 units while the delivery note covers 80. The reviewer still has to work out whether another delivery note is missing, the invoice needs changing, or the terms of the sale explain the difference. Simply spotting the mismatch does not settle it.

In a 2024 case study published by the International Chamber of Commerce, finance provider Air8 said 38% of transactions outside the Li & Fung trading network were sent back for document corrections. The rate was 6% inside the network, where documents used common formats. [2] This comparison covers one provider's own transactions.

OCBC makes same-day processing conditional on the documents being in order, and lets customers add missing files to pending applications. [3] Once those files arrive, someone must check whether they answer the original request. CaseProof will keep that request and the response beside the supporting documents, so the reviewer can see what still needs an answer.

What CaseProof will do

CaseProof will give a reviewer one place to work through an invoice and its delivery records. It will pull out the relevant details, highlight differences and open the exact passages behind each finding. It will also draft a request that the reviewer can edit before asking the business for more information.

In the 100-unit example, the request could ask for evidence of the remaining delivery or a revised invoice. If the business submits an invoice for 80 units, the reviewer can see that the quantity issue has been addressed. A separate disagreement over the company's registration number will stay open. The original invoice and the reason for the change will remain in the case history.

We will start with teams that still review uploaded documents. Each lender's checklist will determine what needs attention. The reviewer will remain responsible for the financing decision; matching documents does not prove that they are genuine.

The first version

The first version will cover finance requests for delivered goods, using an invoice and proof of delivery. A purchase order can provide extra context when available. We will support English PDF files, one currency and up to ten pages per case. Missing or unreadable details will be marked for review.

Google Gemini will read the documents and help draft requests. Separate calculations will check totals and quantities, and quoted text will be checked against the original pages. Google Cloud Run will host the app, with files stored in Cloud Storage. Reviewers will sign in to access their cases and download a summary of what was resolved and what remains open.

Build plan

This plan assumes two people working part-time. Before building the checks, we will ask two or three lending staff to walk through the proposed cases and tell us which requests would actually be useful.

Dates in 2026	Work to complete
24–27 September	Review the cases with potential users; agree on the first set of checks.
28 September–4 October	Build document upload, reading, comparisons and the review screen.
5–8 October	Add requests for corrections, document history and the case summary.
9–12 October	Test complete cases and watch reviewers use the app.
13–17 October	Fix the main problems, record the demonstration and submit.

How we will test it

We will create 60 fictional document sets with known answers. Half will contain deliberate problems; the rest will include valid cases such as partial deliveries. Our initial targets are to find at least 90% of the planted problems and raise false alarms in no more than 10% of the valid cases.

The more important test is what happens after a reply. A correction should resolve the right issue without hiding another one. We will compare similar review tasks done manually and with CaseProof, recording time spent, missed issues and unnecessary requests. We have not yet tested this with lenders; the results will determine whether it saves them work.

All code and example documents will be created during the hackathon. By 17 October, we aim to have a working app, public source code, test results, a short presentation and a demonstration video under three minutes.
